

Problem Statement

The project addresses the limited access to reliable agricultural education for farmers and learners in Central Africa who primarily communicate in local African languages. Much agricultural knowledge is provided in English or French, creating a language barrier for communities that may have limited access to information in these languages. This can reduce access to knowledge about crop management, climate adaptation, sustainable farming, and food security. Our project aims to make agricultural knowledge more accessible through an AI solution designed for underrepresented African languages, initially focusing on languages such as Fulfulde, Bassa, and Hausa. The solution will be guided by inclusion, linguistic and cultural respect, accuracy, safety, and community well-being. Success will not be measured only by model performance, but by whether users can understand and trust the information, access knowledge more easily, and benefit from culturally relevant agricultural education.
